Design of Agentic Systems

AI4FM

AI4FM GPT5.4 Summary

gemini summary

Trust/Quality/Assurance

Human & Ethics

AI should augment human possibilities, be an “enabler” transforming existing, possibly defining new processes - like a tool giving larger reach. How can we define processes that support software engineers, rather than *replace them*?
[Human-centred discipline][Ethics]

If AI can produce 10x pull requests, why aren't 10 more developers hired to check them to avoid overloading a single developer? [Human]

The central question on AI is the question of trust: why can we trust AI artifacts being 'right'? As "to err is human", software engineering came up with many ideas for 'quality control'. Do these ideas carry over to AI artifacts, or do we need new approaches?

In other words, how to estimate the likelihood that the generated artifacts can be relied on?

Can AI be used for checking? Is it ok to use AI for generation against AI for verification? What are the rules¹? What are the methodological principles to ensure the process to be sound? [SE4AI][Trust]

How do we verify neural networks? Can we guarantee properties during machine learning? What properties can we specify? (Maybe <https://doi.org/10.48550/arXiv.2102.06585> is helpful here) (partial answer to 1st question <https://github.com/NeuralNetworkVerification/Marabou>)

What data sets (programs, bugs & fixes) are available? How do we create data sets for training?

- Optimization: <http://github.com/timm/moot> $\leftarrow$ 120+ multi objective problems. paper: <https://arxiv.org/pdf/2511.16882>
- Fairness and privacy: 50+ data sets in table9 of <https://dl.acm.org/doi/10.1145/3652155>
- stuff like defects4j?: <https://github.com/rjust/defects4j> or for security, secbench
